streams process and product models are needed to formulate compositions for an extremely wide variety of elemental species and composition ranges. The demand for process and product models which can predict over such a diverse composition space requires mechanistic understanding of glass behavior. Atomistic simulation is ideally suited for providing this understanding. Moreover, while simulation cannot completely eliminate the need for treatability studies, it can play a role in minimizing the experimentation on and therefore the contact handling of such materials. This paper briefly reviews the molecular dynamics method, which is the primary atomistic simulation tool for studying glass structure. We then summarize the current state of glass simulation, emphasizing areas of importance for waste glass process product modeling. At SRS, glass process and product models have been formulated in terms of glass structural concepts. Atomistic-simulations of Silicate Glasses Seung Ho Hahn, 2020. Silicate based glasses are one of the most versatile materials in terms of technological perspective with a wide range of industrial applications. In most cases, glass products are exposed to various aqueous environments, either humid air or liquid water, and subject to physical contact with foreign objects, which leads to deterioration of chemical and mechanical properties of glass surfaces. Therefore, understanding their interactions with adsorbed interfacial water molecules is critical, as it can provide physical insights needed for rational design of more durable glasses. Experimental characterization approaches have been applied to tackle difficult problems associated with the complex nature of glass surfaces, but they are often limited by the time scale resolution. As a result, they have failed to offer important structural characteristics and chemical reaction mechanisms under dynamic processes happening at the glass surface. To complement the challenges that experimental endeavors are encountering, this dissertation aims to provide a comprehensive understanding of water interactions of silicate glass surfaces using atomistic scale simulations techniques. In particular, ReaxFF reactive force field based molecular dynamics MD simulations are employed to study two distinct surface phenomena: i) surface water reaction and ii) surface mechanochemical wear process. These studies represent the surface damage process of silicate glass in the absence and presence of mechanical actions, respectively. The first part of this dissertation describes the water interactions of a silicate glass with readily leachable alkali sodium ions. In this study, highly complex surface chemistry, including proton water exchange with the sodium ions, formation of relatively long living sodium hydroxide ionic complexes at the glass surface, and eventual dissolution of those ion pairs into the water phase, are described. Also, surface mapping of water binding energy to the glass surface is evaluated at different stages of the glass water reaction, which would be relevant to assess the chemical durability of the glass materials based on the glass network topology. After the transport behavior and glass water reaction mechanism at the surface has been identified, the mechanochemical wear process of sodium silicate glass rubbed with amorphous silica in the absence and presence of interfacial water molecules is covered in the second part of this dissertation. The effect of water molecules on the shear induced chemical reaction at the sliding

interface was investigated and the dependence of wear on the number of interfacial water molecules in ReaxFF MD simulations was found to be qualitatively in reasonable agreement with the experimental data. The large scale atomistic simulation approaches with ReaxFF reactive force field presented in this dissertation alleviates the limitations of DFT calculations and experiments providing new and meaningful insights on the chemical dynamics associated within the glass water interface.

Optical Constants of Inorganic Glasses Andrei M. Efimov, 2020-01-29. This book is devoted to the problem of the frequency dispersion of optical constants of inorganic glasses. It is the only source providing a comprehensive discussion of this topic on a unified physical and analytical basis. *Optical Constants of Inorganic Glasses* presents thorough descriptions of the underlying physical phenomena, analytical models for the optical constants dispersion and detailed information on the optical constants and related optical characteristics of glasses. The broad scope of the book includes such topics as general relationships for the response of a solid to the effect of an electromagnetic field and specific features of optical spectrum formation for a glass and the resulting constants. The text details methods for reconstructing the spectra of optical constants from raw experimental spectra of glasses and provides data on the spectra of optical constants in the IR and VUV ranges and on the IR band parameters for inorganic glasses. It includes factors responsible for the behavior of the refractive index dispersion of glasses in the transparency range. The reference fully details the opportunities provided by the recent version of dispersion analysis for glasses based on the specific analytical model for the complex dielectric constant. Until now this information was only available in Russian journals. A large quantity of never before published data on numerical values of optical constants in the medium and far IR and of IR band frequencies and intensities is given for a wide variety of inorganic glasses. For vitreous silica data on the optical constants are also given for the broad wavelength range in the VUV. *Optical Constants of Inorganic Glasses* provides the only comprehensive review of available dispersion formulas and methods for interpolating and extrapolating the refractive indices.

of glasses in the transparency range The volume is a valuable resource for researchers practitioners in the fields of glass technology

Atomistic simulations provide a necessary lens through which to characterize nanoscale phenomena This dissertation begins with a description of molecular models and the development of an interatomic potential for benzene which incorporates atomic level anisotropy This model was made possible for bulk benzene systems through the implementation of a software plugin for the OpenMM simulation package which enables custom force expressions with atomic level anisotropy This initial discourse on force field development summarizes the types of interatomic potentials used in simulations and avenues for improved accuracy This knowledge of fundamental force field development is transferrable to developing approaches in modeling inorganic crystallization Solid phase epitaxy SPE is a crystal growth technique which employs low temperature annealing conditions to exact kinetic control over the final grown structure In this dissertation classical simulations are used to rigorously define the mechanism of epitaxial growth in strontium titanate over patterned substrates Modeling SPE is challenging from a simulation perspective because long timescales at experimental growth temperature exceed computational feasibility The enhanced sampling method metadynamics is presented here as a viable alternative for probing crystallization mechanisms in super cooled and viscous systems for which diffusion is limited Gaining mechanistic information from metadynamics is dependent on the goodness of reaction coordinate Here an XRD based coordinate is used to distinguish not only between the amorphous and crystal structures but also among metastable crystal polymorphs This dissertation summarizes work which encompasses research spanning molecular models and inorganic crystallization with added commentary on outreach and communication
