**Non-conforming Coupling and Shape Optimization of Complex Multipatch Structures, Volume 1** Robin Bouclier, Thibaut Hirschler, 2022-06-06 Isogeometric analysis IGA consists of using the same higher order and smooth spline functions for the representation of geometry in Computer Aided Design as for the approximation of solution fields in Finite Element Analysis Now about fifteen years after its creation substantial works are being reported in IGA which make it very competitive in scientific computing This book provides a contemporary vision of IGA by first discussing the current challenges in achieving a true bridge between design and analysis then proposing original solutions that answer the issues from an analytical point of view and eventually studying the shape optimization of structures which is one of the greatest applications of IGA To handle complex structures a full analysis to optimization framework is developed based on non invasive coupling parallel domain decomposition and immersed geometrical modeling This seems to be very robust taking on all of the attractive features of IGA the design analysis link numerical efficiency and natural regularization giving us the opportunity to explore new types of design *Isogeometric and CAD-based Methods for Shape and Topology Optimization: Sensitivity Analysis, Bézier Elements and Phase-field Approaches* Jorge Alberto López Zermelo, 2022\* The Finite Element Method FEM is widely used in engineering for solving Partial Differential Equations PDEs over complex geometries To this end it is required to provide the FEM software with a geometric model that is typically constructed in a Computer Aided Design CAD software However FEM and CAD use different approaches for the mathematical description of the geometry Thus it is required to generate a mesh which is suitable for FEM based on the CAD model Nonetheless this procedure is not a trivial task and it can be time consuming This issue becomes more significant for solving shape and topology optimization problems which consist in evolving the geometry iteratively Therefore the computational cost associated to the mesh

generation process is increased exponentially for this type of applications The main goal of this work is to investigate the integration of CAD and CAE in shape and topology optimization To this end numerical tools that close the gap between design and analysis are presented The specific objectives of this work are listed below Automate the sensitivity analysis in an isogeometric framework for applications in shape optimization Applications for linear elasticity are considered A methodology is developed for providing a direct link between the CAD model and the analysis mesh In consequence the sensitivity analysis can be performed in terms of the design variables located in the design model The last objective is to develop an isogeometric method for shape and topological optimization This method should take advantage of using Non Uniform Rational B Splines NURBS with higher continuity as basis functions Isogeometric Analysis IGA is a framework designed to integrate the design and analysis in engineering problems The fundamental idea of IGA is to use the same basis functions for modeling the geometry usually NURBS for the approximation of the solution fields The advantage of integrating design and analysis is two fold First the analysis stage is more accurate since the system of PDEs is not solved using an approximated geometry but the exact CAD model Moreover providing a direct link between the design and analysis discretizations makes possible the implementation of efficient sensitivity analysis methods Second the computational time is significantly reduced because the mesh generation process can be avoided

**Integrated Structural Analysis Using Isogeometric Finite Element Methods** Michael Schwedler, 2016 The gradual digitization in the architecture engineering and construction industry over the past fifty years led to an extremely heterogeneous software environment which today is embodied by the multitude of different digital tools and proprietary data formats used by the many specialists contributing to the design process in a construction project Though these projects become increasingly complex the demands on financial efficiency and the completion within a tight schedule grow at the same time The digital collaboration of project partners has been identified as one key issue in successfully dealing with these challenges Yet currently the numerous software applications and their respective individual views on the design process severely impede that collaboration An approach to establish a unified basis for the digital collaboration regardless of the existing software heterogeneity is a comprehensive digital building model contributed to by all project partners This type of data management known as building information modeling BIM has many benefits yet its adoption is associated with many difficulties and thus proceeds only slowly One aspect in the field of conflicting requirements on such a digital model is the cooperation of architects and structural engineers Traditionally these two disciplines use different abstractions of reality for their models that in consequence lead to incompatible digital representations thereof The onset of isogeometric analysis IGA promised to ease the discrepancy in design and analysis model representations Yet that initial focus quickly shifted towards using these methods as a more powerful basis for numerical simulations Furthermore the isogeometric representation alone is not capable of solving the model abstraction problem It is thus the intention of this work to contribute to an improved digital collaboration of architects

and engineers by exploring an integrated analysis approach on the basis of an unified digital model and solid geometry expressed by splines In the course of this work an analysis framework is developed that utilizes such models to automatically conduct numerical simulations commonly required in construction projects In essence this allows to retrieve structural analysis results from BIM models in a fast and simple manner thereby facilitating rapid design iterations and profound design feedback The BIM implementation Industry Foundation Classes IFC is reviewed with regard to its capabilities of representing the unified model The current IFC schema strongly supports the use of redundant model data a major pitfall in digital collaboration Additionally it does not allow to describe the geometry by volumetric splines As the pursued approach builds upon a unique model for both architectural and structural design and furthermore requires solid geometry necessary schema modifications are suggested Structural entities are modeled by volumetric NURBS patches each of which constitutes an individual subdomain that with regard to the analysis is incompatible with the remaining full model The resulting consequences for numerical simulation are elaborated in this work The individual subdomains have to be weakly coupled for which the mortar method is used Different approaches to discretize the interface traction fields are implemented and their respective impact on the analysis results is evaluated All necessary coupling conditions are automatically derived from the related geometry model The weak coupling procedure leads to a linear system of equations in saddle point form which owed to the volumetric modeling is large in size and the associated coefficient matrix has due to the use of higher degree basis functions a high bandwidth The peculiarities of the system require adapted solution methods that generally cause higher numerical costs than the standard procedures for symmetric positive definite systems do Different methods to solve the specific system are investigated and an efficient parallel algorithm is finally proposed When the structural analysis model is derived from the unified model in the BIM data it does in general initially not meet the requirements on the discretization that are necessary to obtain sufficiently accurate analysis results The consequently necessary patch refinements must be controlled automatically to allow for an entirely automatic analysis procedure For that purpose an empirical refinement scheme based on the geometrical and possibly mechanical properties of the specific entities is proposed The level of refinement may be selectively manipulated by the structural engineer in charge Furthermore a Zienkiewicz Zhu type error estimator is adapted for the use with isogeometric analysis results It is shown that also this estimator can be used to steer an adaptive refinement procedure

**Isogeometric and CAD-based Methods for Shape and Topology Optimization: Sensitivity Analysis, Bézier Elements and Phase-field Approaches** Jorge Alberto López Zermeno, 2022 The Finite Element Method FEM is widely used in engineering for solving Partial Differential Equations PDEs over complex geometries To this end it is required to provide the FEM software with a geometric model that is typically constructed in a Computer Aided Design CAD software However FEM and CAD use different approaches for the mathematical description of the geometry Thus it is required to generate a mesh which is suitable for FEM based on the CAD model Nonetheless this

procedure is not a trivial task and it can be time consuming. This issue becomes more significant for solving shape and topology optimization problems which consist in evolving the geometry iteratively. Therefore the computational cost associated to the mesh generation process is increased exponentially for this type of applications. The main goal of this work is to investigate the integration of CAD and CAE in shape and topology optimization. To this end, numerical tools that close the gap between design and analysis are presented. The specific objectives of this work are listed below:

- Automatize the sensitivity analysis in an isogeometric framework for applications in shape optimization.
- Applications for linear elasticity are considered.
- A methodology is developed for providing a direct link between the CAD model and the analysis mesh. In consequence, the sensitivity analysis can be performed in terms of the design variables located in the design model.
- The last objective is to develop an isogeometric method for shape and topological optimization. This method should take advantage of using Non Uniform Rational B Splines (NURBS) with higher continuity as basis functions.

Isogeometric Analysis (IGA) is a framework designed to integrate the design and analysis in engineering problems. The fundamental idea of IGA is to use the same basis functions for modeling the geometry (usually NURBS) for the approximation of the solution fields. The advantage of integrating design and analysis is two fold:

- First, the analysis stage is more accurate since the system of PDEs is not solved using an approximated geometry but the exact CAD model.
- Moreover, providing a direct link between the design and analysis discretizations makes possible the implementation of efficient sensitivity analysis methods.
- Second, the computational time is significantly reduced because the mesh generation process can be avoided.
