preferential attachment triadic closure and node fitness which are all special cases and thereby provides a flexible means for
conceptualizing estimating and comparing models The lens of discrete choice theory also provides several new tools for
analyzing social network formation In large network data logit models run into practical and conceptual issues since large
numbers of alternatives make direct inference intractable and the assumptions underlying the logit model cease to be
realistic in large graphs Importance sampling of non chosen alternatives reduces the data size significantly while under the
right conditions preserving consistency of the estimates A model simplification technique called de mixing whereby mixture
models are reformulated to operate over disjoint choice sets reduces mixed logit models to conditional logit models This
opens the door to the other approaches to scalability and provides a new analytical toolkit to understand the underlying
processes The flexibility of the logit framework is illustrated with examples that analyze several synthetic and real world
datasets including data from Flickr Venmo and a large citation graph The logit model provides a rigorous method for

estimating preferential attachment models and can separate the effects of preferential attachment and triadic closure A more substantial application is the identification of the persistent and changing parts of the networking strategies of U S college students as they go through their college years This analysis is done using a rich and large data set of digital social network data from the Facebook platform
