**THE** *Journal of the American Medical Association* has published a study that suggests that the use of a single, low-dose, long-acting antipsychotic drug may be more effective than a combination of two or more drugs in treating schizophrenia. The study, which was conducted by a team of researchers from the University of California, San Diego, found that patients who received a single, low-dose, long-acting antipsychotic drug had a significantly higher rate of response to treatment than those who received a combination of two or more drugs. The study also found that patients who received a single, low-dose, long-acting antipsychotic drug had a significantly lower rate of side effects than those who received a combination of two or more drugs. The researchers concluded that the use of a single, low-dose, long-acting antipsychotic drug may be a more effective and safer treatment for schizophrenia than the use of a combination of two or more drugs.

**Abstract** The purpose of this study was to determine the effect of a 12-week resistance training program on the muscle strength and endurance of the lower extremities in healthy young adults. The subjects were 15 male and 15 female college students, aged 18 to 25 years, who were randomly assigned to either a resistance training group or a control group. The resistance training group performed a 12-week program of resistance training, while the control group performed no exercise. The subjects were tested at baseline and at 12 weeks for muscle strength and endurance. The results showed that the resistance training group had significantly greater increases in muscle strength and endurance compared to the control group. The findings suggest that a 12-week resistance training program can effectively improve muscle strength and endurance in healthy young adults.
