Prefabrication for Affordable Housing fib Fédération internationale du béton, 2011-01-01 The need for housing has increased significantly during the last decades all over the world It is felt particularly in countries where the population growth rate is high and the economy is developing fast but everywhere people are shifting from the countryside to towns where housing in neighbourhoods often becomes critical The need for affordable housing may concern high rate urbanization rural areas to be upgraded workers settlements in remote regions rebuilding dwellings destroyed by disasters such as earthquakes floods or wars and even holiday resorts and leisure dwellings Large projects always face cost and time constraints Local conditions may be variable with respect to the physical social and economic environment Thus minimising cost and time of construction while maximising quantity and quality of product may lead to different solutions The concept of affordable meaning compatibility of demand and means is well understood as such everywhere although its practical application may be much different from place to place Concrete is a material that lends itself well to affordable housing it is durable has good thermal inertia can be used both as structural and finishing material and is not sensitive to organic attack It also has some disadvantages such as higher cost in developing countries compared to developed countries and also a potential lack of materials mainly cement or admixtures Prefabrication with its adaptability and quality consciousness may offer valid speedy cost efficient and sustainable solutions fib Bulletin 60 offers an overview of housing systems as well as

information on their features It shows the main features of a number of construction systems without entering into the details of the solutions It aims to make possible a comprehensive comparison which should help in learning exchanging and developing ideas on how to better meet the housing needs everywhere at sustainable cost A document of this kind was not available before it is therefore expected to be of great interest and a source of ideas for all those who have to confront similar problems

Effects of Increasing the Allowable Compressive Stress at Release of Prestressed Concrete Girders David Barra Birrcher, 2007 **Concrete International**, 2004 *Evaluating the Time-dependent Deformations and Bond Characteristics of a Self Consolidating Concrete Mix and the Implication for Pretensioned Bridge Applications* Kyle H. Larson, 2007 Results of an extensive experimental program conducted to determine the material bond characteristics and time dependent deformations of a proposed self consolidating concrete SCC mixture for bridge girders are presented This research program was completed in three phases The first phase consisted of 15 full scale pretensioned SCC flexural specimens tested to evaluate their transfer and development lengths These specimens included both single strand and multiple strand beams as well as specimens designed to evaluate the so called top strand effect The top strand specimens with more than 20 inches of concrete below the strand were tested to evaluate the current American Association of State Highway and Transportation Officials requirement of a 30% increase in the development length when the concrete below the strand is more than 12 inches Strand end slip measurements used to estimate transfer lengths indicated the proposed SCC mixture meets ACI and AASHTO requirements In addition flexural tests confirmed the proposed SCC mixture also meets current code requirements for development length The second phase was to evaluate the elastic shortening creep and shrinkage properties of the proposed SCC mixture for bridge girders Four bridge girders with an inverted T profile were

used to measure these time dependent deformations In two of the specimens the strands were tensioned to 75% of the ultimate tensile strength simulating a girder at service Strands of the other two specimens were left untensioned to evaluate shrinkage effect of the concrete alone The shrinkage was then subtracted from the fully tensioned specimens and elastic shortening and creep were isolated after relaxation losses were calculated from code expressions In addition the fully tensioned specimens were used to determine transfer lengths of the prestressing strand The final phase of the program was to record strain measurements of the actual bridge girders used in the field Elastic shortening creep and shrinkage prestress losses of the proposed SCC mixture were compared with current design equations Instrumentation of seven pretensioned girders in a five span bridge located in Cowley County Kansas was used to measure time dependent deformations Three of these girders utilized SCC while the other four were cast with conventional concrete
