Abstract This paper describes basic methods of transferring data through serial data buses, using serializer/deserializer (SerDes) as main device in this operation. It explains function of SerDes and different techniques for implementing it.

Keywords: SERDES, Clock and data recovery, High speed SerDes, Parallel clock SERDES, Embedded clock SERDES, Ethernet SERDES, Bit interleaving SERDES

I. INTRODUCTION

The simplest method of transferring data through the inputs or outputs of a silicon chip is to directly connect the datapath from one chip to the next chip. Since data often consist of more than one bit of information, the datapath is more than one-bit wide.

There are two inherent problems of the parallel data bus. The first problem is that a input/output (I/O) pins are required on each chip to transfer the data. The second problem involves meeting timing requirements. Due to these two problems we thought about transforming parallel data to serial stream of data to be able to use serial communications off-chips and on-chips.

Serializers/Deserializers (SerDes) are the main devices which convert parallel data into stream of serial data and send it through a channel.

Serial interconnects form the critical backbone of modern communication systems, so the choice of SerDes can have a big impact on system cost and performance. While the many of choices may seem confusing at first, SerDes devices fall into a few basic architectures, each tailored to specific application requirements. A basic understanding of these architectural differences enables the designer to quickly find the right SerDes for the application. In this paper we examine four distinct SerDes architectures and show how each plays a vital role in today's systems.

II. ARCHITECTURE OF HIGH-SPEED SERDES

High-speed Serializer/Deserializer (HSS) devices are the dominant implementation of I/O interfaces at speed of 2.5 Gbps and higher. Such devices are differentiated from source-synchronous interface in that the receiver device contains a clock data recovery (CDR) circuit dynamically determines the optimal sampling point of the data signal based upon the transition edges of the signal. In other words clock information is extracted directly from the data rather than relying on a separate clock.

Fig. 2 HSS basic block diagram

Fig. 2 illustrate the basic block diagram of the transmit and receive channels of an HSS device. The transmitter serializes parallel data, equalizes it and then drives the serial data onto a differential signal pair of interconnect wires. The receiver consists of a differential receiver, a CDR circuit which may also integrate an equalizer and deserializes the data upon the sample point established by the CDR.

SerDes cores which contain only transmit or only receive channels are called *simplex* cores; SerDes cores which contain both transmit and receive channels are called *full duplex* cores. Note that the terminology "full duplex" does not imply that the electrical interface is bidirectional. Any given electrical interconnect channel has a fixed direction of data transmission. If a protocol application requires "full duplex" communication, then independent transmit and receive channels with independent interconnections are used to implement the interface.

Rockrohr, 2008-12-19 The simplest method of transferring data through the inputs or outputs of a silicon chip is to directly connect each bit of the datapath from one chip to the next chip Once upon a time this was an acceptable approach However one aspect and perhaps the only aspect of chip design which has not changed during the career of the authors is Moore's Law which has dictated substantial increases in the number of circuits that can be manufactured on a chip The pin densities of chip packaging technologies have not increased at the same pace as has silicon density and this has led to a prevalence of High Speed Serdes HSS devices as an inherent part of almost any chip design HSS devices are the dominant form of input output for many if not most high integration chips moving serial data between chips at speeds up to 10 Gbps and beyond Chip designers with a background in digital logic design tend to view HSS devices as simply complex digital input output cells This view ignores the complexity associated with serially moving billions of bits of data per second At these data rates the assumptions associated with digital signals break down and analog factors demand consideration The chip designer who oversimplifies the problem does so at his or her own peril
