adding appropriate generation mutation and crossover operators The resulted stochastic algorithm is employed to adaptively sample mixed integer categorical design spaces The proposed surrogates are compared against traditional independent methods for a set of canonical problems and a physics based rotor craft model on a screened design space Next adaptive sampling algorithms on the developed surrogates are applied to the same problems These tests provide evidence of the merit of the proposed methodologies Finally a multi objective rotor craft design application is performed in a large domain space This thesis provides several novel academic contributions The first contribution is the development of new efficient surrogates for systems with categorical design choices Secondly an adaptive sampling algorithm is proposed for systems with mixed integer categorical design spaces Finally previously sampled concepts can be brought to construct efficient surrogates of novel concepts With engineering judgment design community could apply these contributions to discrete alternative selection and initial design assessment when similar topographical trends are observed across different categories and or concepts Also it could be crucial to overcome the current cost of carrying a set of concepts and wider design spaces in the categorical dimension forward into preliminary design   <u>Science Abstracts</u> ,1995   *Adaptive Sampling Schemes and Bayesian Semiparametric Survival Analysis* Bo Cai (PhD.),2003   *An Adaptive Importance Sampling Algorithm for Bayesian Inversion with Multimodal Distributions* ,2015 Parametric uncertainties are encountered in the simulations of many physical systems and may be reduced by an inverse modeling procedure that calibrates the simulation results to observations on the real system being simulated Following Bayes rule a general approach for inverse modeling problems is to sample from the posterior distribution of the uncertain model parameters given the observations However the large number of repetitive forward simulations required in the sampling process could pose a prohibitive computational burden This difficulty is particularly challenging when the posterior is multimodal We present in this paper an adaptive importance sampling algorithm to tackle these challenges Two essential ingredients of the algorithm are 1 a Gaussian mixture GM model adaptively constructed as the proposal distribution to approximate the possibly multimodal target posterior and 2 a mixture of polynomial chaos PC expansions built according to the GM proposal as a surrogate model to alleviate the computational burden caused by computational demanding forward model evaluations In three illustrative examples the proposed adaptive importance sampling algorithm demonstrates its capabilities of automatically finding a GM proposal with an appropriate number of modes for the specific problem under study and obtaining a sample accurately and efficiently representing the posterior with limited number of forward simulations   **Bayesian Approaches for Adaptive Spatial Sampling** R. L. Johnson,J. Quinn,D. LePoire,A. Huttenga,2005 BAASS Bayesian Approaches for Adaptive Spatial Sampling is a set of computational routines developed to support the design and deployment of spatial sampling programs for delineating contamination footprints such as those that might result from the accidental or intentional environmental release of radionuclides BAASS presumes the existence of real time measurement technologies that provide information quickly enough

to affect the progress of data collection This technical memorandum describes the application of BAASS to a simple example compares the performance of a BAASS based program with that of a traditional gridded program and explores the significance of several of the underlying assumptions required by BAASS These assumptions include the range of spatial autocorrelation present the value of prior information the confidence level required for decision making and inside out versus outside in sampling strategies In the context of the example adaptive sampling combined with prior information significantly reduced the number of samples required to delineate the contamination footprint **Bayesian Sampling for Smoothing Parameter Estimation** Shuowen Hu,2015 Kernel density estimation is one of the most important techniques for understanding the distributional properties of data It is understood that the effectiveness of such approach depends on the choice of a kernel function and the choice of a smoothing parameter bandwidth This thesis has undertaken some important topics in bandwidth selection for kernel density estimation for data that behave in various nature The first issue evolves around selecting appropriate bandwidth given the characteristics of the local data in multivariate setting In Chapter 3 the study proposes a kernel density estimator with tail adaptive bandwidths The study derives posterior of bandwidth parameters based on the Kullback Leibler information and presented an MCMC sampling algorithm to estimate bandwidths The Monte Carlo simulation study shows that the kernel density estimator with tail adaptive bandwidths estimated through the proposed sampling algorithm outperforms its competitor The tail adaptive kernel density estimator is applied to the estimation of bivariate density of the paired daily returns of the Australian Ordinary index and S P 500 index during the period of global financial crisis The results show that this estimator could capture richer dynamics in the tail area than the density estimator with a global bandwidth estimated through the normal reference rule and a Bayesian sampling algorithm The second research project investigates bandwidth selection for multimodal distributions or data that exhibits clustering behaviours Chapter 4 proposes a cluster adaptive bandwidth kernel density estimator for data with multimodality This method employs a clustering algorithm to assign a different bandwidth to each cluster identified in the data set The study derives a posterior of bandwidth parameters based on the Kullback Leibler information and presented an MCMC sampling algorithm to estimate bandwidths The Monte Carlo simulation study shows that when the underlying density is a mixture of normals the kernel density estimator with cluster adaptive bandwidths estimated through the proposed sampling algorithm outperforms its competitor When the underlying densities are fat tailed the combined approach of tail and cluster adaptive density estimator performs the best In an empirical study bandwidth matrices are estimated for the cluster adaptive kernel density estimator of eruption duration and waiting time to the next eruption collected from Old Faithful greyer which is often analysed due to its clustering nature The results again shows clear advantage of the proposed cluster adaptive kernel density estimator over traditional approaches The third topic extends the Bayesian bandwidth selection method to volatility models of financial asset return series The study is motivated by the fact that only limited attention in the literature has been invested on the

estimation of nonparametric nonlinear type of volatility models through a Bayesian approach Chapter 5 presents a new volatility model called the semiparametic nonlinear volatility SNV model Based on financial return series of major stock indices in the world the performance of the proposed volatility model against the competing models are examined in both in sample and out of sample periods The proposed model and the Bayesian estimation method show strong and convincing performance results The study also evaluates the empirical value at risk VaR performance of the competing models The proposed volatility model shows the best performance in most cases   Machine Learning Kevin P. Murphy,2012-08-24 A comprehensive introduction to machine learning that uses probabilistic models and inference as a unifying approach Today s Web enabled deluge of electronic data calls for automated methods of data analysis Machine learning provides these developing methods that can automatically detect patterns in data and then use the uncovered patterns to predict future data This textbook offers a comprehensive and self contained introduction to the field of machine learning based on a unified probabilistic approach The coverage combines breadth and depth offering necessary background material on such topics as probability optimization and linear algebra as well as discussion of recent developments in the field including conditional random fields L1 regularization and deep learning The book is written in an informal accessible style complete with pseudo code for the most important algorithms All topics are copiously illustrated with color images and worked examples drawn from such application domains as biology text processing computer vision and robotics Rather than providing a cookbook of different heuristic methods the book stresses a principled model based approach often using the language of graphical models to specify models in a concise and intuitive way Almost all the models described have been implemented in a MATLAB software package PMTK probabilistic modeling toolkit that is freely available online The book is suitable for upper level undergraduates with an introductory level college math background and beginning graduate students   Adaptive Sampling and Online Enrichment Strategies for RB-Based PDE-Constrained Stochastic Optimization Fabio Hauger,2021
     Adaptive Bayesian Sampling with Application to 'bubbles' Ekaterina Ignatieva,2008   **An Optimization Based Algorithm for Bayesian Inference** ,2015 In the Bayesian statistical paradigm uncertainty in the parameters of a physical system is characterized by a probability distribution Information from observations is incorporated by updating this distribution from prior to posterior Quantities of interest such as credible regions event probabilities and other expectations can then be obtained from the posterior distribution One major task in Bayesian inference is then to characterize the posterior distribution for example through sampling Markov chain Monte Carlo MCMC algorithms are often used to sample from posterior distributions using only unnormalized evaluations of the posterior density However high dimensional Bayesian inference problems are challenging for MCMC type sampling algorithms because accurate proposal distributions are needed in order for the sampling to be efficient One method to obtain efficient proposal samples is an optimization based algorithm titled Randomize then Optimize RTO We build upon RTO by developing a new geometric interpretation that describes the

samples as projections of Gaussian distributed points in the joint data and parameter space onto a nonlinear manifold defined by the forward model This interpretation reveals generalizations of RTO that can be used We use this interpretation to draw connections between RTO and two other sampling techniques transport map based MCMC and implicit sampling In addition we motivate and propose an adaptive version of RTO designed to be more robust and efficient Finally we introduce a variable transformation to apply RTO to problems with non Gaussian priors such as Bayesian inverse problems with Li type priors We demonstrate several orders of magnitude in computational savings from this strategy on a high dimensional inverse problem
